Abstract

Objective(s)
Diabetes mellitus is associated with disturbances of learning and memory and cognitive functioning. Aegle marmelos Corr. from Rutaceae family is widely used in Iranian folk medicine for the treatment of diabetes mellitus. Considering the beneficial antidiabetic and antioxidant potential of A. marmelos, this study was conducted to evaluate the effect of oral administration of A. marmelos on learning and spatial memory in diabetic rats using Morris water maze test.

Materials and Methods
Considering the beneficial antidiabetic potential of A. marmelos, this study was conducted to evaluate the effect of chronic oral administration of A. marmelos as cognitive enhancer, on learning and spatial memory in diabetic rats using Morris water maze test. Male Wistar rats were randomly divided into normal-control, diabetic-control, and A. marmelos-treated diabetic groups (100, 250 and 500 mg/kg, p.o.). Animals were treated for 4 weeks by A. marmelos or normal saline. Diabetes was induced by a single dose i.p. injection of streptozotocin (45 mg/kg). In each group of animals, spatial learning and memory parameters were analyzed.

Results
Clear impairment of spatial learning and memory was observed in diabetic group versus normal-control group. A. marmelos showed dose dependent improvement in spatial learning and memory parameters that swimming time (Escape Latency) in normal-control and A. marmelos-treated diabetic animals rats was significantly \((P<0.01)\) lower than diabetic-control, while swimming speed was significantly \((P<0.05)\) higher.

Conclusion
The study demonstrated that A. marmelos has significant protective affect against diabetes-induced spatial learning and memory deficits. This effect could be attributed to hypoglycemic, hypolipidemic and antioxidant activity of A. marmelos.

**Effect of Aegle Marmelos on Memory**

**Introduction**

Diabetes mellitus is a common metabolic disorder, characterized by hyperglycemia due to an absolute or relative insulin deficiency. Diabetes is associated with functional and structural alterations in the peripheral, as well as the central nervous system (1, 2). Moderate disturbances of learning and memory and complex information processing have been reported in both type 1 and 2 diabetic patients (3-5). *Aegle marmelos* Corr. commonly used as folk medicinal plant in south of Iran but it is indigenous to India. It is a medium sized, armed deciduous tree found wild, especially in dry forests and is also cultivated throughout Iranian subcontinent for its fruit. The globose fruit has smooth, hard and aromatic rinds. The ripe fruit is used for indigestion and stomach pathologies. All parts of *A. marmelos* have been used in ethno-medicine for several medicinal properties: astringent, antidiarrheal, antidiysenteric, demulcent, antipyretic, antiscorbutic, haemostatic, aphrodisiac and as an antidote to snake venom (6-9). Previous studies have discussed that *A. marmelos* is a herbal medicine for the treatment of diabetes mellitus (10, 11). Preliminary report indicates hypoglycemic effect in leaves, seeds and fruits of *A. marmelos* (12-15). Ponnachan et al. have reported that the alkaloid extract from *A. marmelos* leaves can exhibit hypoglycemic effect in diabetic rats induced by alloxan (16, 17). Extract of leaf can reverse the increase in $K_m$ values of malate dehydrogenase enzyme in liver (18) and improved histopathological changes in the kidney and pancreatic tissues of diabetic rats induced by streptozotocin (19). Moreover, changing in glucose utilization, balance of cerebral lipid metabolism and oxidative stress that occurs in diabetes are main reasons for cognitive dysfunction (20, 21). Antioxidant and antidyslipidemic effects of *A. marmelos* also have been reported (22-25) and it suggests that *A. marmelos* could be cognitive modifier.

Thus, treatment with herbal medicine that improve glucose utilization, decrease oxidative stress and modify lipid metabolism, may help to improve learning and memory impairment induced by diabetes. There are no available reports on the action of *A. marmelos* seeds on cognitive tests in diabetic rats, therefore, the effect of aqueous extract of *A. marmelos* seeds on spatial learning and memory in streptozotocin induced diabetic rats has been investigated.

**Materials and Methods**

The principles of laboratory animal care (National Institutes of Health publication No. 86-23, revised 1985) were followed in this study.

**Animals**

Male Wistar rats weighing 200-250 g were provided by the Iranian Razi Institute and were housed in standard cages with free access to food (standard laboratory rodent’s chow) and water. The animal house temperature was maintained at 23±3 °C with a 12 hr light/dark cycle (light on from 06:00 to 18:00 hr). The ethical guidelines for the investigation of experimental animals were followed in all tests. All efforts were made to minimize animal suffering and to reduce the number of used animals.

**Preparation of the plant extract**

Seeds of *A. marmelos* from fresh fruits were collected in August 2007 from south of Iran (Bushehr) and authenticated by the School of Agricultural Sciences, Razi University, Kermanshah, Iran. The fruits were macerated in large amount of water and passed through large pore size sieve to separate seeds. The seeds were shade, dried and rubbed vigorously to remove the last traces of fiber attached to them. The seeds were ground mechanically to make powder. Powdered seeds were extracted with boiling water for 10 hr. The resulting extract was cooled and filtered using Whatman No. 1 filter paper. The filtrate was evaporated to dryness in an oven set at 40 °C. The dried extract was weighed and dissolved in normal saline to a concentration of 200 mg/ml. This extract solution was maintained at 4 °C throughout experiments.

**Induction of diabetes in rats**

Streptozotocin of Sigma Chemical Co. (St. Louis, USA) brands was purchased.
Streptozotocin solution (45 mg/kg) in 0.1 M citrate buffer, pH 4.6 was injected intraperitoneally to fasting rats (26). Fasting blood glucose level (FBG) was estimated at the time of induction of diabetes and checked regularly up to stable hyperglycemia, five days after streptozotocin injection. Depending on their FBG level the severe diabetic animals showing FBG above 250 mg/dl, were studied (27).

Treatment
Diabetic animals were treated with extract (100, 250, 500 mg/kg p.o.) or normal saline (diabetic-control) and normal-control group received the same volume of normal saline orally for 4 weeks. At the beginning and end of study, blood samples were collected and centrifuged. FBG levels were measured by glucose oxidase method (28). After 4 weeks, learning and spatial memory in normal and diabetic rats carried out using Morris water maze (MWM) test. During the MWM test, animals fed same as before but 30 min before the MWM test, animals were in fasting state.

Morris water maze task
MWM was constructed from a circular black colored water tank, 140 cm in diameter and 80 cm in height located in the center of small room and was surrounded by numerous extra-maze cues on the wall in the room. The tank was divided into four quadrants (N, E, W and S) and was filled with water till it has reached 40 cm in depth. The experimenter stood in the south-west corner of the room. Invisible round disk platform (made of plexiglas) 10 cm in diameter were used and was located 1 cm beneath the surface of the water. In the first 4 days of experiment, location of platform was constant throughout the sessions. An automated infrared tracking system (CCTV B/W camera, SBC-300 (P), Samsung Electronic Co, Ltd, Korea) recorded the position of the rat in the tank. The camera was mounted 2.5 m above the surface of the water (29).

A) Handling: Each rats received once daily, 10 min handling period for three days, after which the animals were trained for two days to stand on the platform. On the first day, rats were placed on the platform which was at the center of the tank without water for 60 sec, and on the second day, the rats were placed again on the platform under the same conditions but the tank was filled with water, at room temperature (25±2 ºC). When the rat climbed off the platform, the experimenter guided the rat to go back onto the platform (29).

B) Training procedure: Extra-maze landmarks (window, door, etc.) in the room were spatial cues for learning of platform’s position for animals. The position of the platform was fixed throughout the experiments. The platform was located in the north-west quarter of MWM tank with 20 cm distance from the edge of the tank, and 1cm beneath the surface of water. Each rat was tested for 5 sessions. Each session consisted of 4 trials in a day. In first sessions, a trial began by releasing the rat into the water facing the wall of the tank from one of the four quadrants (north, south, east or west). The sequence of starting location was chosen in a pseudorandom manner by computer in such a way that the starting location was different from the immediate preceding trial. The trial was concluded when the rat found the platform or at 60 sec after start of the trial. If the rat could not reach the platform within 60 sec, the experimenter led the rat to the platform and the rat remained on the platform for 30 sec, then released into the water from the next starting location. After the last trial in each session, the rat was towel-wiped and placed in a drying chamber for 5 to 15 min and then returned to the home cage. For evaluation of accuracy and validity of initial learning, probe trial was performed on the fifth day, in which, platform was expelled and animal during one session (consisting of 4 trials) was released into water exclusively from one of the above mentioned directions (east) that was determined by computer for all rats (29).

LD$_{50}$ experiment
For LD$_{50}$ experiment, four groups of rats of both sex (six animals per group, three females and three males) and weighing about 200-250 g were administered orally a single dose of either 2, 3 or 4 times of effective dose of aqueous extract of seeds of *A. marmelos*. Then rats were observed for gross behavioral, neurologic, autonomic and toxic effects at short intervals of time for 24 hr. Food
consumption, feces and urine were also examined at 2 hr and then at 6 hr intervals for 24 hr (22, 29).

**Data analysis**
Data was expressed as mean±SEM. Statistical analysis was performed using one way analysis of variance (ANOVA) and two-way repeated measures followed by Tukey's test for multiple comparisons. P< 0.05 was the critical criterion for statistical significance (29).

**Results**

**Evaluation of escape latency and swimming speed during training days**
Results indicate that diabetes induced deficiency in learning and spatial memory in animals during the experience. *A. marmelos* administration in a dose dependent fashion reduced escape latency during training days. Also there were differences among experimental groups in the third and fourth days of training. On these days, escape latencies in the normal-control and *A. marmelos* groups were less than diabetic-control group. This difference was statistically significant in the third and fourth day of training (P< 0.001), while there was no statistically significant difference (P> 0.05) between *A. marmelos* 500 mg/kg and normal-control group in either four training days (Figure 1). Results also indicated there was a difference in swimming speed among experimental groups. Post-hoc analysis showed that differences between normal-control (P< 0.001), *A. marmelos* 250 mg/kg (P< 0.01) and *A. marmelos* 500 mg/kg (P< 0.001) versus diabetic-control were significant. Differences in swimming speed between *A. marmelos* 500 mg/kg and normal-control group was not significant (P> 0.05) (Figure 2).

**Evaluation of percentage of presence in target quarter in probe trial**
Presence percentage of animals in target quarter (quarter in which platform was located during training days) in probe trial session was investigated. Results showed that there was a significant difference among groups. This difference was significant (P< 0.05) between diabetic-control group and the other groups (Figure 3).

**Effect of A. marmelos on FBG of severely diabetic rats**
Effect of *A. marmelos* oral administration on FBG has been shown in Table 1. *A. marmelos* administration, dose dependently, reduced FBG and there were differences among experimental groups. Post-hoc analysis showed statistically significant differences between normal-control (P< 0.001), *A. marmelos* 100 mg/kg (P< 0.05), *A. marmelos* 250 mg/kg (P< 0.01) and *A. marmelos* 500 mg/kg (P< 0.001) versus diabetic-control. Differences in FBG between *A. marmelos* 500 mg/kg and normal-control group was not statistically significant (P> 0.05).

LD$_{50}$ experiment

In LD$_{50}$ experiment, the behaviour of the treated rats appeared normal. No toxic effect was reported up to 3 and 4 times of effective dose of the water extract and there were no death in either group.

Discussion

Results of the present study suggest that chronic oral administration of A. marmelos has facilitating effects on spatial learning and memory in diabetic rats in Morris water maze test. A. marmelos administration, during training days, leads to decrease in escape latency and also an increase in the animals swimming speed as compared with the diabetic-control group. In this study A. marmelos seeds extract could reduce FBG that confirm hypoglycemic effect of seeds as discussed earlier (22), but the most effective dose was 500 mg/kg. In previous studies, moderate disturbances of learning and memory and complex information processing have been reported in both type 1 and 2 diabetic patients (3-5). Previous experimental studies on cognitive functioning in animal models of diabetes mellitus, such as streptozotocin (STZ)-induced diabetic rodents, have used several learning tasks. In more complex learning tasks, such as active avoidance T-maze, or Morris water maze, diabetic rodents consistently displayed performance deficits (30-32). A. marmelos is known as herbal medicine for the treatment of diabetes mellitus (10, 11). Pharmacological effects of A. marmelos particularly antidyslipidemic and antihyperglycemic properties (1), suggest a cognitive enhancer trait. Patients receiving lipid-lowering drugs like statins have a reduced risk of dementia and cognitive dysfunction (33). Lipids account for half of the dry matter of the brain and are integral to the myelin sheath and synapses. Anything affects the balance of cerebral lipid metabolism could have profound effects on brain function. High cholesterol is also associated with elevated beta-amylloid, the hallmark of cognitive disorders (20). Experimental studies have shown that cholesterol-fed wild-type rabbits develop memory dysfunction and human studies showed that statin therapy reduces the risk of memory impairment (34-36). In addition, free radical generation and oxidative stress can affect all classes of macromolecules (sugar, lipids, proteins, and DNA), leading inevitably to neuronal dysfunction (21). Moreover, in diabetic animals, impaired glucose utilization and insulin signaling has already been linked to increased oxidative stress and mitochondrial dysfunction in
neuronal cells (37, 38). *Aegle marmelos* has antioxidant properties and effectively reduces the oxidative stress (23, 24). This was evident from a significant decrease in lipid peroxidation, conjugated diene and hydroperoxide levels in serum as well as liver in diabetic rats after oral administration of *A. marmelos* (18, 25).

The result of this study reveals that a regular administration of *A. marmelos* aqueous seed extract for 4 weeks improved learning and spatial memory in diabetic animals in Morris water maze test. The dose of 500 mg/kg was the most effective dose. The LD50 of the extract is high (no death even with 4 times of effective dose) indicating high margin of safety. The fall of FBG in diabetic groups treated with *A. marmelos*, after period of study, further confirms our findings.

**Conclusion**

From this study, we can conclusively state that *A. marmelos* aqueous seed extract had beneficial effects on blood glucose levels as well as improving spatial memory impairment due to diabetes. This effect can be attributed to modification of lipid metabolism and blood glucose level and possibly attenuation of the oxidative stress enhancement of diabetes mellitus induced by streptozotocin. Further pharmacological and biochemical investigations are underway to elucidate the mechanism of the learning and memory enhancement effect of *A. marmelos* seeds.
